

# Numerical Analysis Project 2

Margaret Dorsey

October 24, 2016

## Justification of Method

I elected to use cubic splines due to the discrete nature of the data set - because we have no guarantee of consistent, polynomial-like behavior at the data points, it is likely that a single interpolating polynomial would suffer from erratic behavior in between points to accommodate inconsistencies. Although Bezier Curves would likely provide a smooth, appealing interpolation of the data, because they do not necessarily agree with the data points, we would have less fine control over their behavior which is problematic for precise determination of ideal lighting. With cubic splines, we can make adjustments solely through manipulation of the number, spacing, etc of data points without the need to also tweak control points to get expected behavior.

Additionally, to find  $y$  values corresponding to a given  $x$  value on a Bezier curve, we would need to find the roots of  $x = (1-t)^3x_0 + 3(1-t)^2tx_1 + 3(1-t)t^2x_2$ , giving us the  $t$  corresponding to that  $x$  value, and then use that to calculate  $y(t)$ . Although Newton's method is fast and reliable for cubic equations, it is still preferable to not do more work.

## Computation of Splines

## Plots of Output

Data Set 1

Data Set 2

## Propagation of Error

In order to maintain agreement in the first and second derivative, all of the data points changed, at least slightly, when the center input point was changed significantly (from  $-0.980070$  to  $-0.245820$ ). However, the change in a given point becomes less and less the further away from the incorrect data the point is, so the error does not propagate completely throughout, although it does effect the entire output set.

## Testing and Maximum Error Bound

$$-\cos(x - .2)$$

$$y(x) = \begin{cases} -.94416178 + 0.01328678x + .297544285714286x^3 + .892632857x^2 & x < -.5 \\ -.9800700 - .20216250x + .4617342857x^2 + 0.01027857x^3 & x < 0 \\ -.98007000 - .20216250x + .4617342857x^2 + 0.083021x^3 & x < 0.5 \\ -.9208367857 - .5575617857x + 1.172532857x^2 - .3908442857x^3 & x \geq .5 \end{cases}$$

The maximum error on the interval  $[-1, 1]$ ,  $|\cos(x - .2) - y(x)|$ , is 0.00877438285370491 at  $x = .809398143755132$ .

$$1 - x^2$$

$$y(x) = \begin{cases} -.8571428571x + .8571428571 - .8571428571x^3 - 2.571428571x^2 & x < -.5 \\ 1.00000000000000 - .8571428571x^2 + .28571428571x^3 & x < 0 \\ 1. - .8571428571x^2 - .28571428571x^3 & x < 0.5 \\ .8571428571 + .8571428571x - 2.571428571x^2 + .8571428571x^3 & x \geq .5 \end{cases}$$

The maximum error on the interval  $[-1, 1]$ ,  $|1 - x^2 - y(x)|$ , is 0.0240658925870171 at  $x = -.811419518230411$ .

$$\sqrt{5-x^2}$$

$$y(x) = \begin{cases} 2.1968628571 - .2352308571x - .2160468571x^3 - .648140571x^2 & x < -.5 \\ 2.2360680 - .1776788571x^2 + 0.09759428571x^3 & x < 0 \\ 2.23606800 + 1.387778780781 \times 10^{-17}x - .1776788571x^2 - 0.09759428571 * x^3 & x < 0.5 \\ 2.1968628571 + .2352308571x - .648140571x^2 + .2160468571 & x \geq .5 \end{cases}$$

The maximum error on the interval  $[-1, 1]$ ,  $|\sqrt{5-x^2}-y(x)|$ , is 0.00723274707416888 at  $x = -.812835264258024$ .

### Conclusions

In short, the program approximated all three functions fairly well, producing convincing graphs and relatively small maximum errors on the interval.

### Analysis

Without even calculating the error, it is clear from the plots that the derivative approximation is less accurate than the approximation of the function itself. One cause of this is our natural endpoint condition - the first derivative of the spline at the endpoints is affected by the second derivative going to 0 - we could reduce this error by setting the second derivative at the endpoints to the actual value of the second derivative.

The more pathological problem is that the derivative of an interpolating cubic is necessarily a quadratic - and parabolic approximations simply are not very flexible. Derivative functions that are well approximated by a parabola, like  $-\sin$ , have relatively little error in their approximation, while more error is induced by less suitable derivatives. This error is unavoidable when using cubic splines, and would have to be kept in mind when using them to approximate both the function and the first derivative.
